A REVIEW ON CHARACTERIZATION OF SOLID DISPERSION

Vishakha Sharma
Department of Pharmacy
M.J.P Rohilkhand University,
Bareilly, Uttar Pradesh, India

Abstract— Solid dispersion is a two component system or it can be defined as the drug-polymer interaction. Basically, this system is confined in order to increase the solubility of poor water soluble drugs by making the drug dispersed in a polymer. It is based on the concept that the drug (hydrophobic) is dispersed in an inert water-soluble carrier or polymer (hydrophilic) at solid state. In this review, we summarize our current understanding of solid dispersions by studying its characteristics¹.

Keywords— solid dispersion, scanning electron microscopy, XRD, SEM, FTIR, DSC

I. INTRODUCTION

Solid dispersion is a science of dispersing or a technology in which we disperse a solid matrix into a polymer matrix or a liquid one². This has been widely used in pharmaceutical industries as it has become a useful criterion in bringing up the solubility of poorly soluble drugs. Generally solubility, stability and dissolution problems are associated with many pharmaceutical formulations³. With the upbringing of solid dispersion, the problems associated with the poorly soluble drugs have been diminished to a larger extent. This has not only led the enhanced solubility but also led to the increased dissolution rate and bioavailability of poorly soluble drugs, which in turn will promote the use of poorly, water soluble drugs in pharmaceutical formulation of solid dispersion⁴.

II. CHARACTERIZATION

Characterization methods are generally employed for differentiating between solid solutions and solid dispersions. Some of the methods are described here:

Differential scanning calorimetry (DSC)

It is an analytical technique in which the difference in the amount of heat required to increase the temperature of a sample and reference is measured. With the help of DSC, we can find the melting temperatures⁵. DSC helps to study the thermal behaviour of various substances. Generally, the interaction between the drug and the polymer causes change in exothermic and endothermic peaks⁶. According to the different processing conditions, different thermograms were

observed. Mainly, DSC is used in polymer research for three different types of experiments:

- glass-rubber transition temperature (T_g value) determination.
- Melting temperature and heat (T_m/T_c - value and H_f/H_c -value) determination.
- Cure measurements or reacting systems measurements⁷.

Nuclear magnetic resonance (NMR)

To study solvates, polymorphs, provide quantitative data in both drug substance and drug product and study complicated formulations such as amorphous dispersion can be well studied by nuclear magnetic resonance⁸. It is used to investigate the polymorphism by probing the atoms in the solid state. The changes in chemical shift can be connected with the change in conformation or chemical nature of the compound⁹.

Scanning electron microscopy (SEM)

The shape, morphology, properties of drug crystals like particle size and chemical composition can be explained through the range of parameters obtained by SEM. Scanning electron microscopy (SEM) is widely used in the characterization of amorphous solid dispersions¹⁰.

Thermal gravimetric analysis (TGA)

It is a powerful technique for studying the changes in weight of a sample when heated, cooled or when held at constant temperature. It is used to determine temperature in which drug decay occurs. It can also be used to determine the moisture content in solid dispersion and to measure the weight loss at different temperatures which provides information about the thermal stability¹¹.

Powder x-ray diffraction

It can be used to determine the crystalline phase in a mixed system. The crystallinity phase gives sharp narrow diffraction peaks and the amorphous component gives a broad peak. However, too much crystallinity results in brittleness. It can also be used to screen physical stability, to characterize new forms, to screen crystal and amorphous dispersions.

Fourier transformed infrared spectroscopy

FTIR takes into account the specific absorbance of molecular vibrations for quality assessment. It offers molecular and structural conformation in the solid state by probing vibration of atoms. It can be used to determine the changes in bonding between functional groups, to detect chemical properties and to detect the crystallinity range from 1 to 99% in pure material¹².

III. CONCLUSION

We can improve the solubility of poorly soluble drugs with enhanced bioavailability by the technique of solid dispersion. All the above characteristics or parameters played an important role in formulation of an ideal solid dispersion.

IJEAST

INTERNATIONAL JOURNAL
OF ENGINEERING APPLIED SCIENCE
AND TECHNOLOGY

ABOUT IJEAST

International Journal of Engineering Applied Science and Technology (IJEAST) is a peer-reviewed, open access journal that publishes high-quality research papers in the field of Engineering, Applied Science and Technology.

IJEAST aims to provide a platform for researchers, academicians, and professionals to share their innovative ideas, research findings, and practical experiences with the global scientific community.

FOCUS AREAS

- Engineering
- Applied Science
- Technology
- Innovation & Development
- Interdisciplinary Studies

PEER REVIEWED

All submissions are rigorously peer reviewed to ensure quality.

OPEN ACCESS

Free and unrestricted access to research for all.

GLOBAL REACH

Connecting researchers and professionals worldwide.

TIMELY PUBLICATION

We ensure a swift and efficient publication process.
