Abstract- The social and economic of the nation depend upon fossil fuels such as coal, gas and oil. The depletion of natural resources causes economic problems for the usage of power generation and storage, industrial operations and transportation. Based on these consequences, the development of renewable sources such as solar energy, wind energy, tidal energy, geo-thermal energy and biomass have been increasing for the generation of electricity. Due to rapid development in electronic devices, there is a huge development in the storage devices such as batteries, fuel cells and super capacitors. Among these, hybrid super capacitor is the best energy storing device when compared to other electrochemical cells in terms of all aspects. It is a multifunctional electro chemical device which are highly flexible, stretchable, foldable, wearable, transparent and few more functionalities. This paper discuss about the evolution of hybrid supercapacitors, different types of hybrid supercapacitors, energy densities and power densities of the hybrid supercapacitors, properties, applications in the present generation and their future advancements.

Keywords: Batteries, Super capacitors, Hybrid super capacitors, Flywheel, Pumped Hydro, Pseudo capacitors, Double layer super capacitors.

I. INTRODUCTION

In 1800 Volta discovered that certain fluids would generate a continuous flow of electrical power. This discovery led to the invention of the first voltaic cell which is commonly known as battery. The word “battery” comes from the old French word batteries which means “action of beating”[1-3].

In 1859, the French physician Gaston Plante invented the first rechargeable battery [4] based on lead acid. Until then, all batteries were primary, meaning they could not be recharged. Due to this invention there is huge change in the field of energy storage devices.

Later in 1957, engineers at General Electric Company first experimented with an early version of super capacitor, but there were not succeeded. In 1966 again, standard oil company re-discovered the effect of the double-layer capacitor unexpectedly while doing experiments on fuel cell designs. The double-layer greatly improved the ability to store energy and this lead to the evolution of the super capacitors.

In 1978 “supercapacitors” are used for computer memory backup. In the early 20th centuries researches were started on this supercapacitors by using different materials and manufacturing methods which led to improved performance and reducing cost. Due to this there was a great demand for the super capacitors till now. In order to reduce the disadvantages caused by super capacitors they invented the Hybrid super capacitors [5-7].

In this paper, section 2 discuss about the fundamentals and different types of energy storage system, section 3 discuss about the classification of supercapacitors and comparing different energy storing devices, section 4 discuss about the Hybrid Super capacitors and different types of Hybrid Super capacitors, section 5 discuss about the construction and working of this Hybrid Super capacitors, section-6 discuss about the applications of the hybrid super capacitors, section-7 is the conclusion which gives the summary and overview on the topic.

II. FUNDAMENTALS OF ENERGY STORING SYSTEMS

At present power electronics is became a major part in our life because the electrical devices
are incorporated with power electronics for good performance. For this power electronics applications basically require energy storage devices mainly because to use these devices as the primary energy source for power conversion. At present, the following types of energy storing technologies are generally used for various applications [1-3].

a. Flywheel systems  
b. Battery systems  
c. Superconducting magnetic systems  
d. Pumped-hydro system  
e. Compressed air systems  
f. Super capacitor systems  

**Flywheel systems:**  
In this system energy is stored in the mechanical form and this system is used in power quality applications. The below Figure 1 represents the flywheel.

![Figure 1](image1)

**Battery systems:**  
In this systems energy is stored in electrochemical form and this system is used in power systems for power quality and load levelling applications. The below Figure 2 represents the Battery bank.

![Figure 2](image2)

**Superconducting magnetic systems:**  
In this systems energy is stored in the form of magnetic field form and this system is used in bullet trains. The below Figure 3 represents Bullets Train mechanism.

![Figure 3](image3)

**Pumped-hydro systems:**  
In this systems energy is stored in the form of potential energy and this system is used in reservoirs. The below Figure 4 represents Pumped storage Reservoir.

![Figure 4](image4)

**Compressed air systems:**  
In this systems energy is stored in the form of kinetic energy and this system is used in gas based power plant. The below Figure 5 represents the Compressed air system.

![Figure 5](image5)
Super capacitor systems:

In this systems energy is stored in the form of both electrostatic form and electrochemical form and this system is used in automobiles. The belowFigure 6 represents the Hybrid Buses.

These are some of widely used energy storing techniques in the present’s world but they are lot of other energy storing techniques some of them are Hydrogen storage, Biofuel storage, Latent heat thermal energy storage (LHTES) and Sensible heat thermal energy storage (SHTES) etc. The below Figure 7, represents how the power density and energy density of super capacitors

This figure clearly shows that super capacitors are better than Flywheels and Batteries [6-8].

15. **Risk of explosion**

| There is more risk of explosion in this type of cell. | There is no risk of explosion in this type of cell. | There is no risk of explosion in this type of cell. Because they are highly flexible. | Ref no:2, Ref no:6 |

From the above data it is found that the hybrid super capacitors are having more advantages when compared to batteries and super capacitors. Due to this reasons hybrid super capacitors are having higher scope for ultimate power utilisation in near future.

**Keywords:**

- **Specific /Gravimetric Energy:** It is defined as the battery capacity in terms of weight.
- **Coloumbic Efficiency:** It is defined as the efficiency with which charge is transferred in a system during the electrochemical reaction. It is also called as Faraday’s Efficiency.
- **Volumetric Energy:** The amount of energy stored in a system per unit volume is called volumetric energy.

**III. CLASSIFICATION OF SUPER CAPACITORS**

In order to increase the energy density the researcher’s moved on to some latest technology in super capacitors this refers to hybrid super capacitors. Coming to hybrid super capacitors we higher energy densities and 3-4 times more voltage values when compared to super capacitors. These are cheaper in cost and light in weight compared to super capacitors [9-10].

Coming to super capacitors, super-capacitors can be classified according to its working principle as double layer Super-capacitor, Pseudo capacitors (or) Electro chemical super-capacitor and Hybrid super-capacitor as shown in Figure 8. The hybrid super-capacitor means has two different types of electrodes. One of them is double layer super-capacitor material such as active carbon; the other is electrochemical-super capacitor material such as ruthenium dioxide.

**Figure 8**

**IV. HYBRID SUPER CAPACITORS**

These hybrid supercapacitors are mixture of both batteries and supercapacitors. As this energy storage system based on a battery electrode and a supercapacitor electrode called battery-supercapacitor hybrid (BSH)[11-13].
The above Figure 9 shows how the battery electrode and super capacitor electrode are kept to get hybrid super capacitors.

As it is the combination of both batteries and super capacitors it has high energy densities and high power densities. Below graph compares the energy densities and power densities of various energy storing devices such as batteries, super capacitors [14-16].

Acidic BSH’s are usually obtained by combining lead acid battery and super capacitors. Alkali BSH’s are formed by combining one alkaline type battery electrode and capacitive electrode and neutral electrolytes are employed for Na-ion and Li-ion BSHs. Coming to other types such as organic electrolytes and ionic electrolytes are volatile and flammable so gel-polymer type electrolyte is preferable in BSH because of its compatibility and safe energy storage and they are also popular for their flexibility and stretch ability. Aqueous BSHs are generally cheaper than the organic electrolyte and ionic based BSH’s[21-22].

The electrolyte types and materials resources, aqueous BSH’s (acidic/alkaline BSH, aqueous Li-ion, and redox BSH’s etc are more cheaper than organic electrolyte and ionic liquid-based BSH’s and non Li-ion BSH’s such as Na-ion BSH’s used for long term applications and cheaper than all the above mentioned BSH’s because sodium (Na) is abundantly available on our earth[23].

From the above Figure 10, it is found that hybrid supercapacitors are having higher power densities and energy densities than the other energy storing devices such as batteries and supercapacitors. The hybrid super capacitors are also called as BSH which means battery-super capacitor hybrid [17].

These Hybrid super capacitors (BSH) classified into several types based on the electrolyte components and specific energy storage mechanism. Li-ion BSH, Na-ion BSH, acidic BSH, alkaline BSH, BSH with redox electrolytes, and BSH with pseudocapacitive electrode and the above mentioned types are classified based on electrolytic components present in the BSH[18-20].

The above diagram 11 clearly represents different types of BSH devices and their classifications and the type of materials used in BSHs. For this above mentioned types Lithium based systems was the most popular one compare to others because of their high energy densities and some other chemical properties. So most of the researches are choosing this field which leads to the rapid growth of the Hybrid Supercapacitors.
V. CONSTRUCTION AND WORKING OF HYBRID SUPER CAPACITORS

The hollow nanostructures with complex shell structures are suitable for efficient energy storage of electrochemical energy [24]. Carbon based nano cubes are used for the formation of double shelled hollow structures surrounded by outer shells made of carbon sulphide as shown in the Figure 12. The special arrangements of subunits with different dimensions have high surface area, robustness which gives higher performance as a battery type electrode. Moreover a hybrid super capacitor is fabricated by using CoS-NP/CoS-NS as the positive electrode and the activated carbon as the negative electrode. These devices are operated table in a wide potential range of 1.6v with high energy and power density. This device is stable for 10,000 cycles with an extension of capacitance by 88%.

VI. APPLICATIONS

1. Hybrid Electric Vehicles
2. Micro grids
3. Energy Harvesting
4. Gondola
5. Railways
6. Uninterruptible power supply

Hybrid Electric Vehicles: These Super capacitors are used in electric vehicles increase the charging time, stable electrical properties, broader ranges of temperatures and longer lifetime when compared to batteries. On using these hybrid supercapacitors in hybrid electric vehicles braking energy is stored to improve driving efficiency [27]. This regenerative braking system is used to reduce fuel consumption in electric hybrid vehicles. Supercapacitors provide quick bursts of power, start-stop fuel saving system, faster start-stop with respect to traffic lights. The Figure 13 represents the various processes occurring in a hybrid vehicle.

Micro grids: In micro grids, power is delivered by using clean and renewable energy as shown in the
Figure 14. Supercapacitors are used in microgrids to store the input power and deliver the power required during high demands and this reverse action takes place because of the presence of supercapacitors. Microgrids produce energy in the form of DC whereas supercapacitors are used for both AC and DC applications. These supercapacitors do not provide frequency when the grid is directly connected to the AC [27].

**Energy Harvesting:** Super capacitors are used in energy harvesting sector as shown in the Figure 15 because these are used to storing energy and discharging energy. Here the energy can be stored from different renewable like light energy, solar energy, wind energy and other forms of energy is converted into electrical energy. This stored energy will be released within 10 hours [27].

**Gondola:** These are used in faraway places from cities and are connected between mountains. These gondola use electricity for complete day for opening and closing the door, communication as shown in the Figure 16. These require very fast charging near the stations because it cannot be recharged when it is travelling. Supercapacitors are used in gondola for fast charging, more number of cycles and high lifetime [28].

**Railway:** Supercapacitors are used in starting systems for railways for diesel electric transmission as shown in the Figure 17. These capacitors store braking energy and use it for regenerative action. These supercapacitors deliver peak current and magnetise the supply voltage. This is used in starting systems for diesel engines and increases the speed of the train. The use of supercapacitors in trains increases the efficiency [28].

**Uninterruptible power supplies (UPS):** UPS systems are used to provide continuous and uninterruptible power supplies during peak loads by transferring power supply from the stored or backup energy system when any power disruption occurs. This type of energy transfer requires high energy density batteries so hybrid supercapacitors are highly preferable. There may be increase in battery losses and reduce the life cycle of the battery because of high pulsating currents. But hybrid supercapacitors can withstand high currents and their transients. These hybrid supercapacitors are used in UPS systems when backup system is required and for delivering power in short time. The Figure 18 represents the schematic process takes place for providing uninterrupted power supply.
The review on the above article represents the current status of the hybrid supercapacitors and its future applications in various fields. The classification and principles of hybrid supercapacitors along with their mechanisms are reported in the article. In the field of electrification and transportation, small electronic devices are used for storing large amounts of energy in shorter time but at low cost. The combination of Li-ion batteries and ultra-capacitors shows how efficiency and reliability of the source increases.

These hybrid super capacitors are suggested as best energy storing devices because of their higher energy and power densities. The applications of hybrid supercapacitors are especially used in field of hybrid electric vehicles, uninterruptible power supplies and energy harvesting. Super capacitors are more feasible and sustainable energy storing devices when compared to other energy storing devices like Li-ion batteries, capacitors and supercapacitors. These supercapacitors are fabricated through different types of materials to avoid losses due to resistance and leakage currents. The developments of hybrid super capacitors using different materials have great extent in future.

VIII. ACKNOWLEDGEMENT

I take this opportunity to express my deep sense of gratitude towards my guide Dr. D. Danalakshmi, Associate Professor, Department of Electrical Engineering, GMRIT. I extend my sincere thanks to Dr. B. Bharani Chandra Kumar, Head of the Electrical department, GMRIT. Their motivation, Patience and their encouragement has benefited us to do this research work.
